

In Situ Simulation Sepsis Telehealth Toolkit

The purpose of this toolkit is to guide the process of training health care leadership and bedside staff how to integrate telehealth into the workflow by using in situ simulation as an instructional platform.

**The project and tools described within this toolkit are specifically for using telehealth in rural emergency departments (EDs) to assist with managing sepsis patients. However, the content could be modified for any telehealth implementation within any health care setting.*

What is Sepsis?

Sepsis is a serious and potentially life-threatening and overwhelming body infection that can result in death quickly if medical interventions are not implemented within recommended time frames (ex. antibiotics and fluids administered within three hours of onset and administration of vasopressors within six hours to bring the patient's dangerously low blood pressure back up).

National standards for the diagnosis and treatment of sepsis have been established to guide medical professionals on [appropriate care practices for these critically ill patients](#). Meeting these standards can be challenging for health care professionals as a patient who once appeared stable can decline rapidly. This is where telehealth monitoring can assist in the care of sepsis patients presenting to emergency departments.

What is Telehealth?

Telehealth involves using electronic technologies to support the care of patients remotely. At OSF HealthCare, the telehealth department is known as OSF ConstantCare or the eICU. This team of critical care nurses and physicians support other clinicians in several emergency departments and intensive care units (ICUs) across OSF HealthCare so that another set of eyes is on the patient at all times. These clinicians monitor vital signs, blood and imaging test results and medications ordered or administered in real time from a remote site. They communicate with the bedside health care team when needed.

As a part of this sepsis project, a **telehealth cart** dedicated to the remote monitoring of sepsis patients was made available to two rural OSF HealthCare emergency departments (ED). If rural ED staff suspected a patient might have sepsis, they could bring the cart into the patient's room and utilize additional monitoring from critical care nurses from the eICU. This extra set of eyes is not intended to take over care of the patient, but rather add additional support to the rural ED team. Telehealth allows the ED nurse to continue monitoring other patients without fear of a potential sepsis patient declining rapidly. This previously mentioned process was followed during this particular sepsis telehealth project; however, telehealth equipment would not necessarily always include bringing in a separate cart each time a suspected sepsis patient presented to the ED exam room. Other telehealth technologies could include: 1) an already installed monitor/camera within the exam room which would allow for simply turning on the visual connection between the rural ED and eICU, 2) remote access to the patient's physiology (their blood pressure, heart rate, oxygen saturation, respiratory rate, temperature, heart monitor readings), and 3) simple telephone access between the ED and eICU.

eICU Constant Care Nurse monitors multiple patients in EDs and ICUs across OSF HealthCare.

Our Project:

Part 1: In situ simulation

Jump Simulation collaborated with Northwestern University on a federally funded AHRQ grant between 2016 – 2019 [Agency for Healthcare Research and Quality Grant 1 R18 HS024027-01 “In Situ Simulation for Adoption of New Technology to Enhance Safety in Rural EDs”]. The project involved using in situ simulation to create a training plan with health care staff from two rural EDs to facilitate learning how to incorporate telehealth connections to the eICU within the normal workflow for the care of sepsis patients. Rural EDs were selected because they face unique challenges including smaller nursing and support staff, less physicians and fluctuating patient volumes with differing severity of illnesses. Since sepsis patients can decline rapidly from one moment to the next, having back-up critical care nurses monitoring the patient via telehealth gives rural ED nurses and physicians peace of mind to care for other patients without fear of missing a rapid change in a sepsis patient’s status. The monitoring layer can include cameras, patient physiology as seen on monitors or both.

Image of the sepsis telehealth cart used for real clinical telehealth audiovisual connection and for the in situ simulation connection (our study) between the bedside care team and the eICU team.

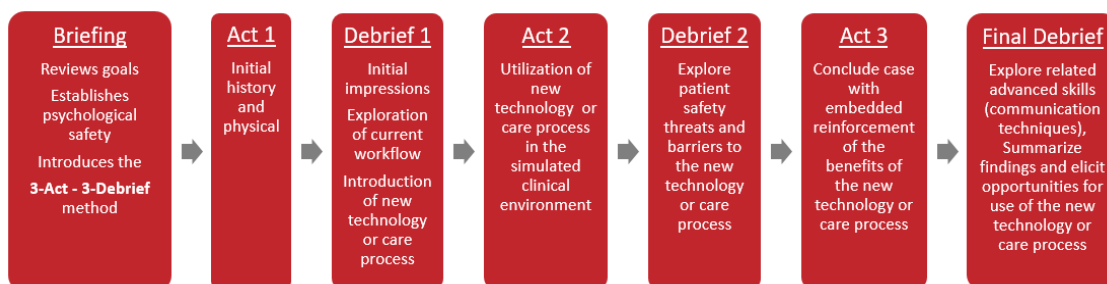

The Jump Research Team and the eICU nurses created and participated in the in situ (on-site) simulation training. An actor known in the simulation world as a standardized participant (SP) played the role of a patient presenting to the ED with possible sepsis. ED staff took turns assessing and monitoring the simulated patient just as they would if it had been a real patient. Labs, imaging, medications and fluids were ordered, and appropriate assessments were simulated on the SP. The scenario was written in three acts, so time for hands-on training with the telehealth interface could be embedded within the sepsis simulation scenario.

Barker, L.T., Bond, W.F., Vincent, A.L. *et al.*
A novel in situ simulation framework for introduction of a new technology: the 3-Act-3-Debrief model
Advances in Simulation 5, 25 (2020).
<https://doi.org/10.1186/s41077-020-00145-x>

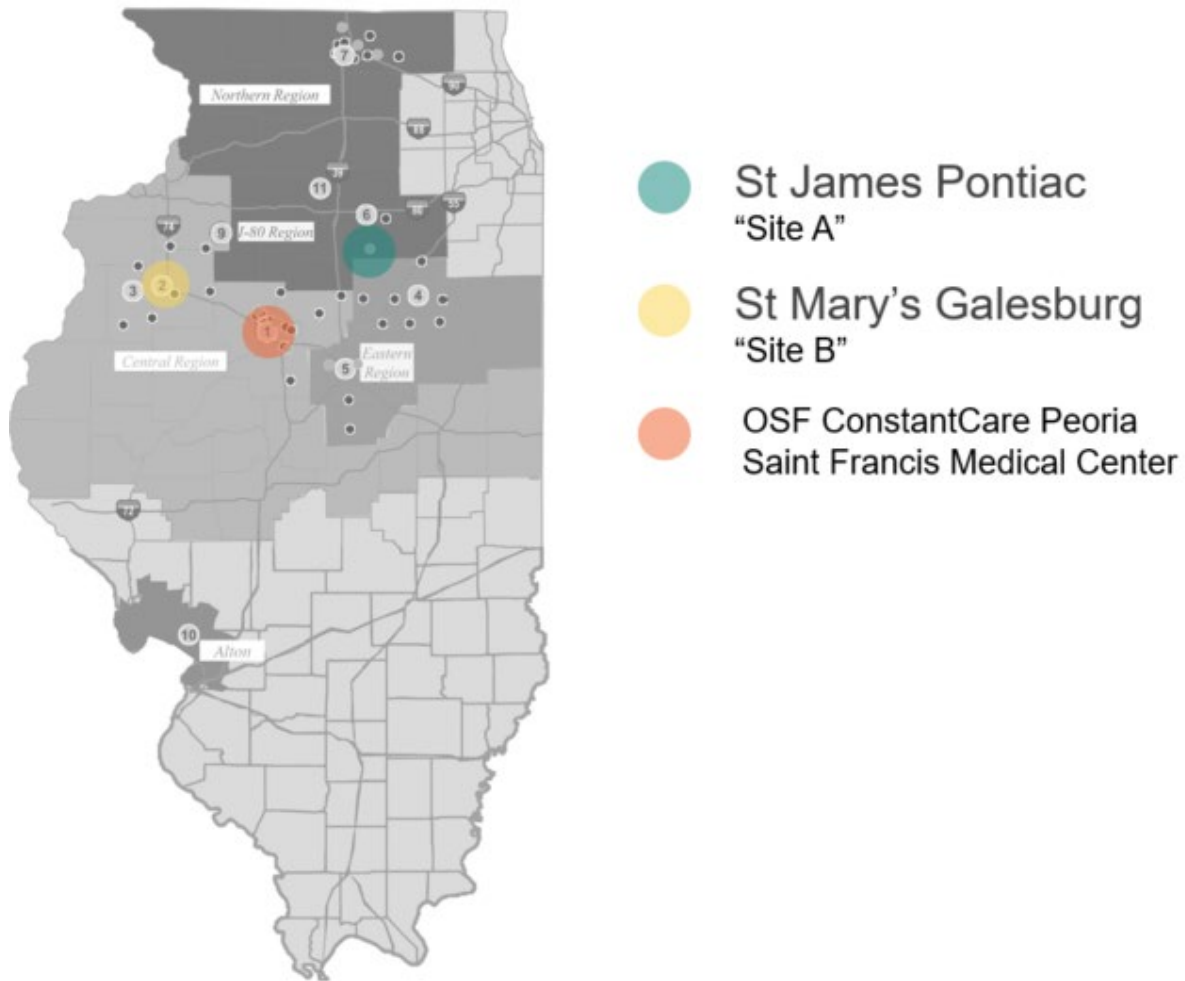

eICU nurses facilitated the sepsis telehealth cart training and actually connected with an eICU nurse at the tertiary care referral hospital that houses the eICU staff. The rural ED staff were allowed to practice using the real cart. During the second act of the simulation, the SP patient continued to decline to simulate how a sepsis patient becomes more ill in the real world. The rural ED staff simulated bringing the sepsis telehealth cart into the patient room at this time. They practiced turning it on again and connected with the off-site eICU nurse. Introductions were made between the remote eICU nurse and SP patient in the rural ED just as it would happen in the real world.

The simulation was paused again, so Jump Simulation faculty could debrief with the rural ED staff on the scenario and telehealth cart. This also gave a place for the eICU to call the rural ED and simulate that the SP patient was showing signs of confusion and low blood pressure. Those clinical signs were an indication the patient was going into septic shock. Staff went back into the simulated exam room to administer vasopressors in attempt to resuscitate the patient. The scenario ended with the SP responding to treatment and rural ED staff and Jump faculty participated with a final debrief.

Both sites received the same sepsis training via an electronic module prior to site A’s initial in situ simulation. Refresher sepsis training and updated best practice alert (BPA) electronic health record (EHR) content was provided via an electronic module prior to site B’s initial in situ simulation and site A’s refresher simulation.

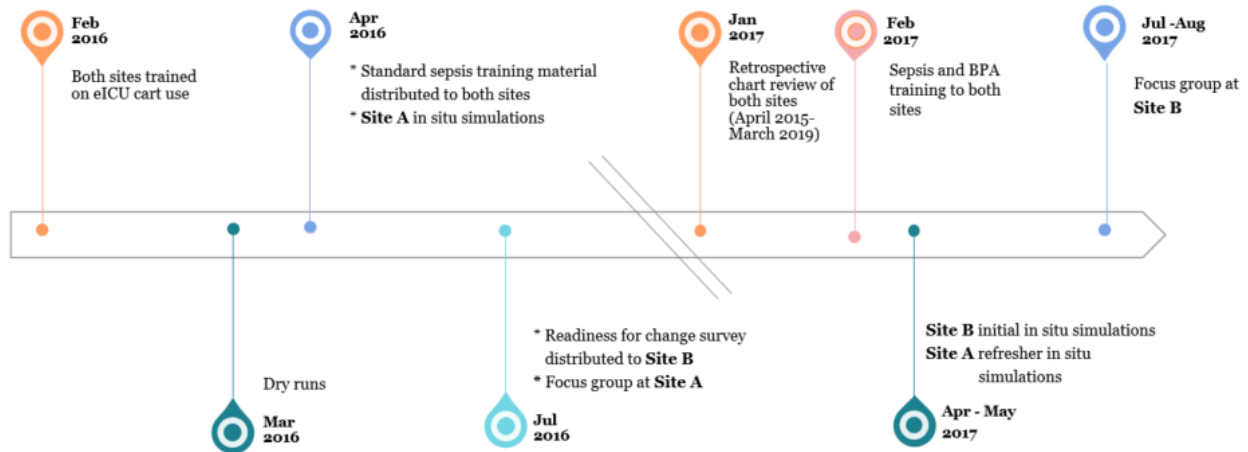

Displays the in situ simulation sepsis scenario flow divided between 3 Acts.

Displays the location of the two rural ED sites who participated in the in situ simulation and the location of the OSF ConstantCare site where the eICU staff is physically located at OSF HealthCare Saint Francis Medical Center.

Part 2: Chart review

Part 2 of the project involved performing a chart review of all sepsis patients seen at both rural ED sites one year before the training through one year after the training. The team wanted to investigate if using the telehealth cart in normal workflow improved treatment and outcomes for sepsis patients.

D. Critical Actions Checklist

This critical actions checklist was used by a Jump Research team member as she observed the in situ simulation taking place in the rural ED. The observer sat in the ED exam room in the corner and brought up the checklist on her laptop. A Microsoft Lync meeting was scheduled between the observer and the eICU nurse who was participating in the in situ at the OSF ConstantCare location in Peoria. By scheduling a meeting using Lync software, the observer was able to share her desktop screen that displayed the blank checklist so the eICU could view it in real-time.

Once the in situ simulation initiated, the observer marked off testing that was ordered and communicated other actions that occurred. This created a low-cost way to provide situational awareness to the confederate eICU nurse off site. Since the eICU nurse was written into the simulation, the nurse needed to know what was ordered during the simulation so she could provide guidance once the rural ED team turned the telehealth cart on. Since the simulation involved three acts, this also provided a means to communicate start and stop points embedded within the simulation.

The screenshot shows a Microsoft Lync meeting window. The main window displays an 'InSitu location' map with markers for 'St. Jame's Pontiac' and 'St. Mary's Galesburg'. Below the map, there are input fields for 'Pre-Brief Start Time (Approximately 10 minutes)' with the value '1520' and 'ACT I Start Time' with the value '1531'. A bolded text block reads: 'ACT I: Goal of Act One is Patient Assessment, identification of SIRS criteria, initiation of septic work-up, and placing on monitor'. Below this is a checklist table with two columns: 'Observed' and 'Not Observed'. The checklist items are: 'Assessment of history by physician and/or nurse' (Observed), 'Patient placed on monitor' (Observed), '2nd IV started' (Not Observed), 'CVC ordered' (Not Observed), 'Antibiotics ordered (name in box below)' (Not Observed), 'CBC ordered' (Not Observed), 'CMP ordered' (Not Observed), 'U/A ordered' (Not Observed), 'Lactate ordered' (Observed), and 'IVF (1 liter) bolus ordered' (Not Observed). To the right, a chat window titled 'Conversation (2 Participants)' shows a message from 'Nelson, Lori R.' saying 'Great, ACT I is starting.' at 3:32 PM, and a reply from 'Nelson, Lori R.' saying 'ok' at 3:32 PM. The chat window also shows a 'Stop Presenting' button and a 'Last message received on 7/24/2018 at 3:32 PM.' notification.

Lactate ordered	<input type="radio"/>	<input type="radio"/>
Repeat Lactate ordered	<input type="radio"/>	<input type="radio"/>
IVF bolus ordered	<input type="radio"/>	<input type="radio"/>
Vasopressor started (any type) _____ (name)	<input type="radio"/>	<input type="radio"/>
Blood culture ordered	<input type="radio"/>	<input type="radio"/>
CXR ordered	<input type="radio"/>	<input type="radio"/>
ECG ordered	<input type="radio"/>	<input type="radio"/>
Antibiotics ordered _____ (name)	<input type="radio"/>	<input type="radio"/>
Labs reviewed	<input type="radio"/>	<input type="radio"/>
Team member vocalizes Septic Shock	<input type="radio"/>	<input type="radio"/>
Free Text Comments _____		
Call made for transfer/admission to ICU (this ends ACT III)	<input type="radio"/>	<input type="radio"/>

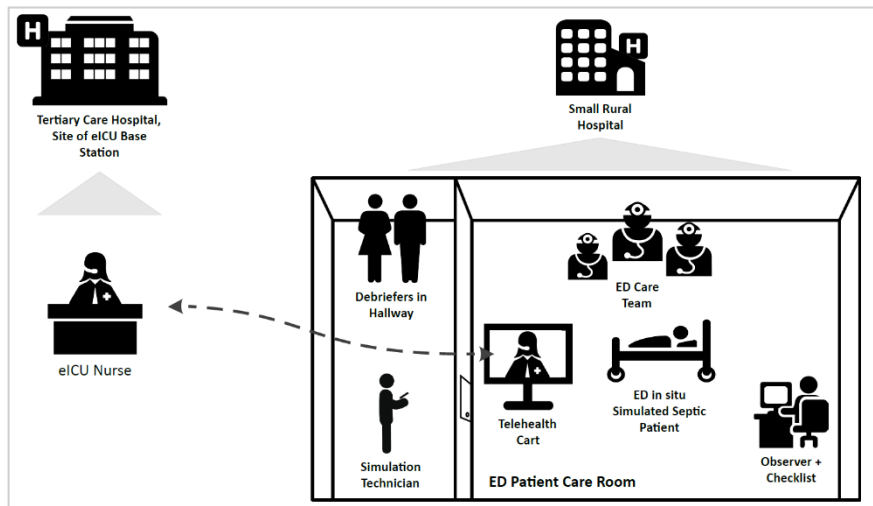

End of ACT III Stop Time _____
 Final Debrief Start Time: _____
All team members plus telehealth present Includes communication strategies, points of contact, conflict communication, details of sepsis hospital concept, barriers vs benefits and when to use. (10 minutes)

Checklist included in Toolkit: [4b Critical Actions Checklist.docx](#)

A member of the research team was present in the ED room where the simulation took place and observed the in situ as it transpired in real time. The observer shared their desktop screen via teleconferencing software with the eICU staff who were located at the tertiary hospital site. The above is an example of the critical action's checklist content shared on the research observer's desktop. As the observer viewed actions occurring, the checklist was completed.

Free text options were available to include notes for special circumstances.

This real time checklist completion method provided the situational awareness needed for successful integration of the eICU staff with the ED during the in situ simulation so they could react accordingly as confederates.

Setting the Stage Guide
Example Verbiage

Introductions

Be sure to immediately start with introductions once all the learners are present and ready to begin. ALWAYS introduce yourself with your credentials. Ex: "My name is Dustin, clinically I am a Paramedic and also a Simulation Specialist with Jump." Be sure the SP introduces themselves also (we usually go around in a circle so everyone can say their name and role).

After introductions, the Clinical Educator or Facilitator will give bits and pieces of the basic assumption and safety contract to the participants and your job is to fill in the gaps. Afterwards, introduce the modality of simulation and make sure they understand the expectations of the event (suspension of disbelief). Here is the entire basic assumption and safety contract so that you can fill in what gets left out:

CAN SIMULATION INFLUENCE WILLINGNESS TO ADOPT TELEHEALTH TECHNOLOGY FOR SEPSIS?

William F Bond MD, MS,¹ Lisa T Barker MD,² William P Tillis MD,² Andrew L Vincent DO,² Jessica Svendsen BA, CCRC,¹ Kimberly Cooley RN, CCRC,¹ Jeremy S McGarvey MS,¹ John A Vozenilek MD,¹ Emille S Powell MD, MBA, MS³

OBJECTIVE

To assess, via survey methods, the influence of in situ simulation on willingness to adopt, and confidence in use of, telehealth technology at two rural emergency departments (EDs) that were encouraged to use telehealth for the care of severe sepsis/septic shock patients.

METHODS

In year one, rural ED1 did the telehealth rollout support simulations, and the technology was made available via standard methods at rural ED2. After one year, ED1 had refresher in situ simulations and ED2 had rollout simulations [Figure 1]. We conducted simulations in a 3-Act-3-Debrief 60-minute format that interspersed training in telehealth use, debrief/discussion of barriers and facilitating factors, and review of sepsis care. Our sample size goal was 80% nurse participation. Readiness to adopt telehealth technology was evaluated at each time point by 6 questions (content areas - improving quality of care, feasibility, role clarity, ease of use, resources, and receptiveness to use) selected from a previously validated survey using a 5-point Likert scale (1 = strongly disagree, 5=strongly agree). Separate Mann-Whitney U Tests were used for ED 1, comparing pre vs. post simulation and pre-refresh vs. post-refresh simulation [Figure 2]. The K-W rank sum test was used for ED 2, comparing initial, pre and post surveys [Figure 3]. Self-confidence ratings (10 point scale) for rollout simulations only were compared with paired t-tests [Figure 4].

RESULTS

Enrollment targets were met for participation at ED1 (20 nurses, 5 providers, 5 others) and ED2 (22 nurses, 4 providers, 4 others). See telehealth survey results in [Figure 2-3] and learner confidence changes pre-post simulation in [Figure 4].

CONCLUSIONS

In situ simulation is a promising method to influence willingness to adopt telehealth technology in the care of septic patients. Reduced willingness found 12 months post simulation intervention may in part be due to changes in staff and simulation participants, and more frequent refreshers may help train new staff and solidify gains. Many other barriers and facilitating factors likely contribute to telehealth engagement, and future efforts should qualitatively explore influences of use and quantitatively assess the impact of this training via tracking telehealth use, care process change markers, and clinical outcomes.

eICU at OSF Healthcare

Rural in situ ED

eICU nurses participated in the simulations at the rural EDs via the telehealth cart.

2015: Oct, Nov, Dec (Both sites retrospective chart review sepsis)

2016: Jan, Feb, Mar, Apr (Both sites, in-situ telehealth roll-out; Dry Run; Both sites standard sepsis training; ED1: in-situ simulation)

2017: May, Jun, Jul, Aug (ED 1: baseline for change survey initial survey for the 30000 remaining staff; ED 2: baseline for change survey initial survey for the 30000 remaining staff; Both sites: standard sepsis training; ED 2: in situ simulation; ED 1: refresher simulation)

2018: Sep, Oct, Nov, Dec (Both sites retrospective chart review sepsis)

ACKNOWLEDGEMENTS:

The Jump Simulation Team would like to acknowledge Emilie Powell, MD, MBA, MS from Department of Emergency Medicine, Northwestern Memorial Hospital, Northwestern University Feinberg School of Medicine for leading this project.

The authors would like to acknowledge:

- Simulation Specialist: Dustin Holzwarth
- Jump Simulation Research Assistants: Gabriel Beratio, Rebecca Ebert-Allen, Blair Engerman, Dipen Kumar, Kyle Mou and Chase Salazar
- Jump Simulation Standardized Participant Program
- OSF ConstantCare eICU staff: William Tillis, MD; Toni Bortell, RN; Sarah Metzger, RN; Lori Nelson, RN; Courtney Pilat, RN; Erika Shaw, RN; and Vicki Weatherington, RN
- Rural ED Leadership: Erin Nimbler, RN and Lisa Sopher, RN
- Emergency department staff from OSF HealthCare Saint James - John W. Albrecht Medical Center in Pontiac and OSF HealthCare St. Mary Medical Center in Galesburg who participated and provided feedback during the study
- We also wish to thank co-investigators Andrew Vincent, emergency medicine physician, OSF HealthCare, and John Vozenilek, MD, vice president and chief medical officer of Innovation and Digital Health, OSF HealthCare.

Emilie Powell, MD, MBA, MS
[Northwestern Medicine Profile](#)

Dr. Emilie Powell, Standardized Participant and eICU nurse practice the sepsis simulations before implementing them in the rural EDs.
